General

Attention
These installation, commissioning and maintenance instructions must be read and observed by all people who carry out work on the unit. For components which are not described, the individual instructions are to be observed (request if required). robatherm will not be held liable for damage or faults which result from non-observance of these instructions. The manufacturer’s warranty and the certificate of installation/conformity do not apply for unofficial or unapproved conversions and changes to the appliance.

Use for Intended Purpose
The unit supplied by robatherm must only be used for air handling. This includes filtering, heating, cooling, humidifying, dehumidifying and transporting of air. robatherm expressly forbids any other use.

Units with the „Ex“-mark (subsequently described as ATEX-units) are to be used in accordance with the unit identification on the nameplate and on the technical data sheet in accordance with the ATEX directive. Be sure to observe any restrictions on use.

ATEX units must not be used near:
- High frequency sources (e.g. transmitters)
- Strong light sources (e.g. lasers)
- Ionising radiation sources (e.g. X-ray tubes)
- Ultrasound sources (e.g. ultrasound echo testing equipment)

Mechanical Equipment Room
The requirements of mechanical equipment rooms must be observed in accordance with the VDI 2050 for operations and maintenance. This also includes sufficient maintenance space, ventilation as well as compliance with the temperature and humidity requirements. In front of heating and cooling coils, it is recommended to allow an obstacle-free area, at least as wide as the AHU’s depth for maintaining those coils.

Transport and Storage
All units and components must be transported and stored in such a way that damage, adverse effects through weather factors, condensation (ensure sufficient rear ventilation within the packaging) or contamination are avoided. When storing for over 3 months, loosen belt drives and turn rotating components such as e.g. on ventilators, motors, pumps, HRS rotors on a monthly basis.

Installation
If units are supplied in separate sections, these shall be assembled in accordance with these assembly instructions and professionally connected to the ductwork. All protective devices shall be applied.
The person responsible for assembly on site and changing non-runable components to complete ready to operate units is also responsible for issuing the certificate of conformity and the CE marking.

Before Commissioning
The unit can only be taken into operation if it has been assembled in accordance with these instructions. All protective devices must be effective. A lockable service switch must be installed near the fan unit access door.
Fire Protection
Possible spreading of fire between supply- and exhaust air sections of the AHU (e.g. via the heat recovery system or recirculating air) must be prevented by appropriate precautionary measures in the building site's system (e.g. fire dampers) by others. A possibly required down gradient grid, according to DIN EN 1886 and AHU-Guideline 01, must be installed within the system to prevent any carry-over of flammable parts from filters, mist eliminators or contact humidifiers into the supply air duct.

Handover
AHUs with integrated control technology may only be taken into operation after robatherm’s initial commissioning and after handover and customer’s briefing has been concluded.

Freeze Protection
In case of ambient temperatures below the freezing point, it can make sense not to switch down the unit, e.g. in order to prevent dampers from freezing or to avoid any failures during a later restart.
Safety Instructions

Caution
Serious bodily injuries and even loss of life and material damage can result from non-
observation of the following instructions of the valid national and international safety
regulations.
References in this document to technical rules (e.g. BGR, BGV, DVGW, TRBS, TRGI) are
subject to the relevant local health and safety regulations regarding installation and
operation of the unit.
Even if the unit is switched off, certain regulating functions can lead to sudden switching on
of unit components such as e.g. resumption of power supply, compressor pump-out, fan
overshoot, frost protection, timer programs.

When the fan is in operation, there is perilous voltage on the permanent-magnet
synchronous motor --> danger to life.

Do not commission ATEX units until the following requirements are met:
- Conditions of use in accordance with the purpose for which the unit is intended.
- No substances nearby that are prone to spontaneous combustion e.g. pyrophoric
  substances under EN 1127-1.
- Constant and adequate ventilation of the installation site (mechanical equipment room)
  in the case of ATEX units without a specified exterior ex zone so that unavoidable
  leakage to the exterior of the unit does not result in an explosive atmosphere.

Only enter the unit or work on it when the following conditions are met:
- All-pole disconnection of power supply.
- Minimum waiting period of frequency converter 15 minutes (due to remaining voltage).
- Use a switch-off device to prevent unexpected start-up (e.g. service switch) according to
  DIN EN 60204-1 (VDE 0113-1).
- Standstill of all moving parts, especially fan impeller, belt drive, motor, rotary heat
  exchanger.
- Heat exchanger and hydraulic systems adapted to ambient temperature.
- Pressure bearing systems must be free of pressure.
- Wear protective clothing.
- No explosive atmosphere present. (rinse unit beforehand if necessary)

The following requirements must be met before the unit is switched on:
- Protective devices must be fitted and effective in accordance with DIN EN ISO 12100
  (e.g. protective grille).
- Check that no persons are in the danger area, e.g. inside the unit.

Work must only be carried out by a qualified expert.
The floor loading in the AHU must not exceed 100 kg/m² of floor surface.

Basically, the units’ roof is not designed to any additional load. In case of need, please
contact robatherm directly.
Emergency Provisions

Fire
The local fire provisions must generally be complied with. If there is a fire, disconnect all-pole power supply to the unit immediately. Close dampers and fire dampers in order to stop the oxygen supply and the spread of fire. Direct fire-fighting and first aid measures immediately. Inform the fire brigade. Protection of people has priority over protection of property.

Caution
Serious damage to health or even loss of life if fire gases are breathed in. In a fire building materials used may generate toxic substances. Use heavy duty breathing protection!

Serious damage may be caused to health and property by bursting of pressure vessels or pipelines during a fire. Keep away from danger area!

Maintenance and Cleaning Instructions

Equipment
When performing maintenance and cleaning work in explosion hazard zones, only suitable tools which e.g. prevent sparks may be used in accordance with EN 1127-1. Conductive footwear must be used to prevent personnel from accumulating static charge in accordance with TRBS 2153.

Maintenance Intervals
AHUs are machines which require regular maintenance. The maintenance intervals given are approximate and relate to normally polluted air according to VDI 6022. If air is heavily polluted, the maintenance intervals must be shortened accordingly. Regular maintenance does not absolve the operator from his duty of care which involves checking the unit for function and damage on a daily basis.

Cleaning and Maintenance of the Casing (including Pans)
- Coarse contamination must be removed dry with an industrial vacuum cleaner.
- Other fouling: Use damp cloth; with grease and oil dissolving cleaners if necessary (neutral cleaner with pH value between 7 and 9 in the concentrate).
- To completely clean pans with limited accessibility, (eg. under coils) obstructive elements might have to be disassembled prior to cleaning.
- Treat galvanized parts with preservative spray.
- All moving parts such as door handles, hinges must be treated with lubricating spray regularly.
- Check sealings, especially door sealings regularly for damage and function.
- Immediately eliminate damage to the coating or traces of corrosion by using touch up paint.
- Remove pollution and dirt in gaps or grooves using damp cloth with applicable cleansers or a vacuum cleaner.
To prevent danger of ignition due to electrostatic charge, all surfaces of ATEX units may only be cleaned with a damp cloth.

**Disinfectants**
Only use disinfectants with an alcohol base with country specific approval (e.g. RKI, VAH, DGKH).

**Recommissioning**
After carrying out maintenance or disinfecting measures, ensure the unit is sufficiently clean before returning to operation. Toxic or odorous substances must not come into the supply air.

**Leak Test**
In clean areas where there must be no transfer of particles from exhaust air to supply air, the relevant parts must be tested for leakage annually or following any servicing (e.g. by means of a suitable test gas). Observe manufacturer’s safety instructions! If necessary take suitable measures to eliminate any leaks in consultation with the manufacturer.

**Supply of Spare Parts / Customer Service / Repair**
Changes to the unit must only be carried out by qualified personnel. After carrying out changes (e.g. installation of spare parts) a new assessment of conformity must be carried out in accordance with the health and safety requirements of the ATEX guideline by a qualified person with the relevant documentation before the unit is switched back on. Spare parts must meet the specific requirements of the ATEX classification applied (category, atmosphere, temperature classification). It is preferable to use identical original components. If inappropriate changes are made to the unit by third parties, the robatherm declaration of conformity ceases to apply.
Delivery

Goods Inspection
On receipt of the goods they must be checked for damage and completeness. Missing parts and damage must be noted immediately on the consignment note and be confirmed by the driver. Details relating to procedures when damage is discovered are noted in detail on the delivery note. If no such procedures are followed, no liability for defects will be accepted.

Unloading and Transport

All units are equipped with lifting eyes or transport loops.
Units without their own base frame are equipped for transportation with expendable pallets.
Only transport unit in usage position (not inclined or lying).
Unloading and transport should preferably be carried out with a crane or fork lift truck.

Caution
Serious bodily damage or material damage may be caused by falling loads.
Observe the safety instructions of the transporting vehicles.
Do not stop under an airborne load!
Unloading and Transport by Crane

Attention
Only use suitable and approved slinging devices (ropes, chains, lifting belts) for unloading and transporting the units and only fasten them to the lifting eyes or transportation loops in accordance with BGV D6.

Unloading by Means of Lifting Eyes (image to left)
Fasten slinging device to lifting eyes. If the angle of inclination between the slinging device and load is less than 45°, then a lifting harness is to be used.

Unloading by Means of Transport Loops (image to right)
The transport loops must be used for unit parts which are fully mounted on a DIN-frame.

For DIN-frame units with six transport shackles and by means of a suitable onsite lifting equipment (e.g. cargo gear), it is imperative that an even load distribution on all transport shackles must be ensured.
Unloading and Transport by Fork Lift Truck

Attention
When unloading and transporting with fork lift trucks, use forks which go fully underneath the unit. Only transport units on the base frame or on the pallet.
Assembly and Installation

Unit Installation

Attention
robatherm units must not take on any functions of the building itself. If a unit is misused, for example by substituting base of unit for building roof or by allocating static functions to the unit, all warranty obligations on the part of robatherm will lapse. Observe the notes in VDI 3803.

Attention
For reasons of mechanical durability, stability and wind load stability, it is not permitted to install different air handling units directly one above the other (stacking) without a suitable sub-construction provided by the customer. If the AHUs are installed differently from the above, the warranty claim expires.

Foundation
Install units on a firm and flat foundation. Any unevenness, leading to non-parallel frames of connecting parts, must be flattened out with suitable supports (metal strips or equivalent). Maximum tolerance to the horizontal is $s = 0.5\%$ (max angle of inclination: $0.3^\circ$).

The foundation must conform to the building requirements in terms of statics, acoustics and proper water drainage (drip pan, air humidifier, etc.). Structural beams must be one single piece over their entire length. The maximum beam distortion is $1/1000$ of the beam length. The distance between horizontal beams may not exceed 24 modules (2.5 m).

The natural frequency of the supporting structure, especially steel supports, must be separated adequately from the exciter frequency of rotating components of e.g. fans, motors, pumps, compressors etc,

Standing Safety
Units installed outside must be secured to the foundations in accordance with the expected wind speed at the place of installation. This applies for all units with integrated motor extraction device.

Lifting Gear
Only use suitable and permitted lifting gear for assembly. Only apply lifting gear at the top edge of the base frame to avoid any deformations.
Mechanical Equipment Room
The requirements of mechanical equipment rooms must be observed in accordance with the VDI 2050 for operations and maintenance. This also includes sufficient maintenance space, ventilation as well as compliance with the temperature and humidity requirements. In front of heating and cooling coils, it is recommended to allow an obstacle-free area, at least as wide as the AHU’s depth for maintaining those coils.

Note
Check arrangement of functional components and unit design in accordance with data sheet and drawing prior to starting unit installation.

Sound Reduction
In order to adhere to the permissible sound emission values, sound reducing components are to be installed at suction and pressure points or on the unit housing (e.g. duct sound damper, sound proofing walls) if they are not or insufficiently integrated into the unit.

Structure Borne Sound Insulation
Unit bases for structure borne sound insulation e.g. Mafund, Silomer or Ilmod Kompri Band are to be used in a lengthways and downwards direction.

Base Frame with Thermal Break
Misalignment of the casing connecting holes through different compression of the decoupling profile on the basis of weight differences of neighbouring appliance parts must be balanced out for unit installation e.g. by means of suitable lifting gear.

Lifting Eyes / Transport Loops
Following assembly remove the lifting eyes / transport loops and seal the openings by means of plugs.
Unit Connection

All connecting parts such as screws, sealing tapes and roofing strips (only for weatherproof units) are included in the units – mostly in the fan unit.

The unit sections are connected by bolts used through the inside. If no access doors are provided at connection points, the marked covering panels must be removed for better access.

If unit sections are only accessible from one side, there will be threaded bushes in the frame. For the stainless steel version only use stainless steel connecting elements.

Through Bolt Connection

Bolt with Thread Bushes

In order to connect the unit parts, proceed as follows:
- Stick self-adhesive sealing along the circumference of the section frame at each division area of a unit
Note
The sealing must be stuck between the covering panel and the row of holes.
- Cut out holes or threaded bushes in the sealing.
- If necessary remove marked covering panels.
- If necessary press unit parts together with screw clamps.
- Connect components.
- Refit covering panels which have been removed.

Sealing of Unit Section Joints
For residue free cleaning of the unit, all unit casing splits in the base area are to be sealed with microbially inert PU jointing compound.

Units in Weatherproof Version
All unit openings (e.g. duct discharge, electrical connecting box etc.) must be sealed or equipped with weather protection in order to prevent water ingress into the unit. Do not position the suction and discharge openings in the main wind direction. Plan the installation height of the unit in accordance with max. snow level. Connected ducts must be drained professionally on site.
All air ducts shall be installed stress-free. Any flexible connectors must not be extended to their max length. Adjust its installation length at 100 to 120 mm. Air ducts including connection profiles and flexible connectors should be professionally insulated and protected from the elements. Provide the same to the units’ frames.

**Flexible Connection**

1 – Unit frame, 2 – Flexible connection, 3 – Building duct

**Decoupled Section Frame**

1 – Unit frame, 2 – Decoupled section frame, 3 – Building duct, 4 – Sealing
Equipotential Bonding

Attention
To prevent ignition through electrostatic charge all electrically non-conductive connection points must be by-passed with equipotential bonding, e.g. decoupled section frame, flexible connections, vibration isolation. All metallic parts of the units must be included in the local equipotential bonding measures. The unit must be earthed on the base frame in accordance with current best practice (foundation electrode). For this purpose a bore hole at the base frame or a rivet on the floor (for units without base frame) is provided for ATEX units and marked with an earthing sticker. All connections must be secured against coming loose.

Lightning Protection of Outdoor Installations

For reasons of operating safety a suitable lightning conductor system must be provided in accordance with local regulations (e.g. DIN VDE 0185).

Connection of Heat Exchangers

When connecting heating and cooling water piping (inlet and outlet), care must be taken to ensure that the inlet and outlet connections are not confused (counterflow principle with water inlet and air outlet side).

Connection of the Heating and Cooling Water Piping – Example

1 – Inlet, 2 – Outlet, Arrow – Direction of Air
Attention

Plan and fit pipework to and from the unit so that the heat exchanger is not subject to stress and strain e.g. as a result of heavy weights, vibration, tensional forces, heat expansion etc. Use compensators if necessary.

When tightening the threaded connections of the heat exchanger on site use e.g. a pipe wrench for counter pressure as the inner pipes may otherwise be twisted and damaged.

The pipes must be flanged in such a way that problem free removal of the heat exchangers for maintenance or exchange purposes is possible.

Connection of Refrigerating Piping

Prior to connection check the heat exchangers and pipes for leaks, i.e. whether the inert gas charge on the operation side is still under pressure.

Connection of the Condensate, Discharge and Overflow Piping

Provide all outlets with a siphon (with non-return valve and self-filling device) and remove waste water appropriately. The height of the siphon must be set in accordance with the low pressure or overpressure of the ventilation unit so that suction or blowing out of the air in relation to the connected waste water pipe is prevented. The water must flow directly from the siphon into a catch pit or funnel. Do not under any circumstances connect the siphon directly to the sewage network.

Connection Siphon

1 – Opening for recharge, 2 – Do not connect any horizontal extension
Calculation of Siphon Trap
The height of the siphon is determined as follows:

Under pressure in the device:
H₁ (mm) = p/10
Hₛ (mm) = p x 0.075

Overpressure in the device:
H₁ (mm) = 35 mm
Hₛ (mm) = (p/10) + 50
p = Unit pressure in Pa (always enter positive value)

Connect siphon directly to appropriate connection and fill with water.

Connection Air Washer
Separately connect drainage pipe of washer and outflow of pan at the front at the waste water duct.

Electrical Connection

Attention
Electrical work must only be carried out by a qualified expert.
Make sure that the electrical connection of weatherproof units is water tight. Connection from below or waterproof unions (at least protection rating IP 65, use sealings) with sufficient cable radius.
Check all electrical connections (switch cabinet, frequency converter, motor etc.) for correct seating and retighten if necessary (see also DIN 46200).

Electrical components such as electric air heaters, electric motors, actuators, etc. should be connected and grounded according to manufacturer’s specifications, local electrical regulations as well as general recommendations concerning the prevention of electromagnetic interferences (grounding, cable lengths, cable shields, etc.).
The connection tags are attached in the terminal box.
All existing ground straps (equipotential bondings) shall be inspected and, if necessary, readjusted/retightened.
Electrical safety inspections should take place in accordance with DIN EN 60204 (VDE 0113) and by adhering to all required safety precautions.
The on-site power supply must fulfill the requirements cited in DIN EN 60204, Table 10. According to nationally valid regulations, the operator is obligated to repeat these inspections on a regular basis.
In Germany, the periodic intervals of the repeated inspections according to BGV A3 §5 Table 1A (Repeated inspections of stationary electrical units and equipment) must be observed.
Motor Protection

- Protect motors against overload in accordance with DIN EN 60204 (VDE 0113).
- Provide motor protection switch and adjust to the motor nominal current (see nameplate). A higher set value is not permissible!
- Protect motors with integrated PTC thermistor sensors via a PTC release device.
- Motors with a nominal power up to 3 kW can generally be switched on directly (observe power limitations of the responsible energy supply company). For larger motors provide star-delta circuit or soft start up.
- Permanent-magnet synchronous motors must not be operated directly on the net without extra motor electronic (e.g. appropriate frequency converter) (net-bypass-operation is not possible).

Motors which are operated in an explosive atmosphere and with a frequency converter must be equipped with an ATEX tested PTC control element. The correct connection of the motor and with it the application of a tested monitoring element must be assured by the customer/operator.

Attention
Fuses and circuit breakers are not sufficient motor protection. For damage due to insufficient motor protection the manufacturer’s warranty lapses.
Clean Up

When assembly is complete all components must be inspected for contamination and cleaned if necessary in accordance with VDI 6022. Metal swarf in particular must be removed carefully as it can lead to corrosion.

Caution
Observe general safety instructions on page 3!

Access Door

On completion of the assembly work all access doors must be checked for freedom of movement. Depending on the operating conditions it can be necessary to align the access doors accordingly. Bolt torque: 3 Nm.

- Hinge side (image left): The long holes in the hinge carrier enable vertical alignment of the door leaf, the long holes in the hinge bracket allow horizontal alignment.
- Lock side (image right): Following alignment of the door leaf on the hinge side, an adjustment of the outer lock may be necessary. For this purpose the ramp of the closing cam can be adjusted vertically and the closing housing horizontally.

Rotary Heat Exchanger

For rotor housings which are supplied separately the rotor housing must be bolted in position as instructed by the rotor manufacturer prior to installation of thermal mass. For this it is necessary to lower the upper rotor housing accordingly.

Assembly of Rotors

In case assembly of a rotor is provided by the customer, the client is responsible that the connection between rotor and unit casing will be professionally made and tightened (e.g. with elastic joint seal).
Sealing of the Roof of Weatherproof Units

General

The roofs of the weatherproof units are covered with plastic strips. If units are supplied separately for easier transportation, division areas must be sealed as instructed in the following work sequence.

The following material is supplied:
- Plastic roofing strips.
- Solvent welding material (adhesive).
- PVC solution (sealing).
- Pieces of coated sheet metal for overlaps.

Safety Regulations

Caution

Solvent welding material and PVC solution are slightly volatile and flammable. The following regulations are compulsory while using them:
- Injuries caused by fire or deflagration! Naked flame and smoking are forbidden.
- Damage to health caused by solvent vapours. Avoid inhaling!
- Solvent welding material and PVC solution are to be kept in hermetically sealed vessels and open containers must be used quickly.
- Storage must be frost free and protected from light.

Work Process

Laying of Roofing Strip

1 – Roofing strip; 2 – Flat brush; 3 – Overlap; 4 – Division area; 5 – Solvent welding material; 6 – Roof cover sheet; 7 – Abutting edge

- Remove lifting eyes and seal hole with plugs (if required shift the base profile in the roof panel a little).
- Laying temperature ≥+10 °C; pre-heat with industrial blower for temperatures <+10 °C.
- The roofing strip must be clean and absolutely dry alongside the division area.
- Dry damp roofing strips with industrial blow drier.
- Place the overlapping pieces (3) on division area (4) above the drip nose and bolt or rivet on.
Installation

- Seal sections of max. 100 mm, for this:
  - Apply solvent welding material (5) with a flat brush (2) in direction of laying directly in front of the roofing strip (1) approx 5 to 10 cm on the roof to the right and left of the division area.
  - Immediately press on the roofing strip with the flat of your hand and place heavy weight (e.g. sand bag) on adhesion points.
  - Repeat work process. The weight need not be left on the adhesion points for a long time.
- Seal the abutment edges (7) of the roofing strip with the PVC solution, for this:
  - Squeeze the plastic bottle and press the PVC solution continuously into the edge as a thin strand. The solution quickly dries into a compact film.
- Close transport lug openings as described.

Note

If it rains during unit assembly the roof must be covered with a tarpaulin for example.
Damper

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
Do not grip into damper as there is a danger of crushing to limbs! Protection devices such as e.g. duct connection, protective grille etc. must be present in accordance with DIN EN ISO 12100.

Only use approved actuators with ATEX units. All electrical parts must be earthed.

Attention
Do not switch on fan before checking that the appropriate damper is open or that its opening is indicated by a position switch. Provide a control linkage so that when a damper closes, the fans affected are switched off immediately. robatherm accepts no liability for damage due to incorrect operation.
Provide pressure relief dampers to prevent damage from pressure spikes due to fire dampers in the system.

Backflow
Appropriate actions need to be taken to avoid backflow from the building.

Coupled Dampers
If dampers are coupled, check friction locking and proper functioning linkage, i.e. direction of rotation and end position of dampers.
Check for proper tightening of all screws and connections.

Motor Driven Dampers
For drive by servo motor: Set linkage so that there is a rotational angle of 90 degrees and the dampers reach their end position on closing.
Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
Do not grip into damper as there is a danger of crushing to limbs! Protection devices such as e.g. duct connection, protective grille etc. must be present in accordance with DIN EN ISO 12100.

**Dampers – Periodic Maintenance**
- Check dampers for function, contamination, damage and corrosion
- Check effectiveness of protective device

**Dampers – Maintenance when necessary**
- Clean dampers and rectify any damage and corrosion

**Dampers with Linkage Drive – Periodic Maintenance**
- Check secure seating and easy movement of linkage
- Check adjustment

**Dampers with Linkage Drive – Maintenance when necessary**
- Grease brass bearings (plastic bearings do not need to be greased)
- Grease linkage

**Note**
Do not grease or oil dampers with a toothed drive.
Fan and Motor

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
Serious bodily injuries or even loss of life and material damage can be caused by the breakage of the impeller. Do not exceed maximum fan speed as per nameplate and technical data sheet. Do not operate fan if there are abnormal vibrations. There is a danger of fire through grinding impeller, belt, hot running bearings. Danger to health through noise (up to approx. 110 dB).

Only use approved parts with ATEX units. All electrical parts must be earthed.

Transportation Safety Device
Remove transportation safety devices (wooden wedges or locking plates) from base frame of fan. Avoid pulling vibration isolators.

Attention
Before commissioning check unit and duct system for foreign bodies (tools, small parts, building dust) and clean if necessary. Rotate impeller by hand to check for free running.

Plug Fans
During transportation the circumferential gap between the impeller and inlet nozzle may change. Measure the gap width before commissioning. The gap must be the same width round the whole circumference; if necessary correct the gap at the vibration damper using lock nut and adjusting nut (1). The overlap (R) must be about 1% of the impeller diameter. There is no need to perform this check for an open impeller with flexible connection.
Drive
Check friction locking of bushes and hubs (see torque settings).

Check V-belt drive and adjust if necessary
- Belt tension (see page 28).
- Alignment of belt pulleys (tolerance < 0.4°; d.h. < 7 mm/m).

After a running in phase of 1 to 2 hours:
- Retighten V-belt (see page 28). When retightening check for exact alignment of the belt pulleys and adjust if necessary.
- Check the securing screws of bushes and hubs for correct seating and retighten if necessary (see torque settings).

Direction of Rotation
Check fan direction of rotation is in line with direction arrow on casing by switching on the motor briefly. If the fan rotates in the wrong direction, reverse polarity of the motor in accordance with the safety regulations.
**Current Consumption**

After reaching the fan operating speed immediately measure the current consumption of all three phases with closed inspection openings. The measurement values must not exceed the rated values on the nameplate (and with it the motor nominal power) and only vary slightly from one another. If there is a current overload switch off immediately and check external pressures, airflow rate and rotational speed. If phase current is unequal, check motor connection.

**Attention**

In order to avoid any vibration fractures, fans may not be operated at unacceptably high speeds (see below) and also not in the field of the resonance speed (and multiples of it) of the fan motor system. Therefore resonance speeds are to be established on commissioning and blanked at the frequency converter. Rebalance if necessary.

Fans may not be run outside the operating range stated by the manufacturer. The manufacturer’s acceleration and delay times must be observed.

There is a danger of fire through grinding impeller, belt, hot running bearings.

**Working on Fan Motor Assembly**

During work on fan motor assembly, e.g. bearing replacement, fitting of plug fan etc., the separate assembly instructions must always be followed (ask for them to be forwarded if necessary!). After this the vibration speed of the unit must be checked, assessed and balanced if necessary.

**Caution**

Serious bodily injuries or even loss of life and material damage can be caused by the breakage of the impeller. Do not operate fan if there are extreme vibrations or unacceptably high vibration speeds.

Assessed limits for vibration velocity $v_{eff}$ under VDI 2056 and DIN ISO 10816:

Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Maintenance Instruction**
The maintenance interval must be shortened accordingly if there is a multi-shift operation and/or special operating conditions such as fluid temperature > 40 °C, appearance of dust etc.

If one or more V-belts fail in a multiple groove drive, then a new V-belt set must be fitted. Prior to fitting the V-belts, the axle base must be reduced so that the belts can be placed in the grooves without force. Forcible fitting by means of a screwdriver etc. is in any case not permitted as it can lead to damage.

**Caution**
Observe general safety instructions on page 3!

**Cleaning Agent**
Cleaning agent shall have a pH value between pH 7 – pH 9.

**Fan – Periodic Maintenance**
- Check fan for hygiene, contamination, damage, corrosion and fastening
- Check impeller for imbalance and vibrations; balance if necessary
- Check bearings for noise, vibration and heat
- Check flexible connection for leaks
- Check functioning of vibration dampers
- Check function of protective devices
- Check function of inlet vane control
- Check functioning of dehydration equipment
- Check gap width of open impellers (see page 23); correct if necessary
- Pollution and dirt on flex connector shall be removed with a vacuum cleaner, and, in a second step, wiped with a with damp cloth

**Fan – Maintenance when necessary**
- Replace bearings (no later than the end of the theoretical service life)
- Grease bearing. Follow manufacturer's instructions!
- Clean fan, rectify any damage and corrosion, retighten fastenings

**Electric Motor – Periodic Maintenance**
- Check electric motor for contamination, damage, corrosion, fastening, smooth running, heating and direction of rotation
- Check bearings for noise, vibration and heat
- Clean electric motor and rectify any damage and corrosion
- Measure tension, current input and phase symmetry
- Check firm seating of terminals in terminal block; retighten if necessary
- Check protective conductor; retighten or replace if necessary
- Check cable rails. Clean it if necessary with vacuum cleaner and, if necessary with damp cloth
**Electric Motor – Maintenance when necessary**
- Replace bearings (no later than the end of the theoretical service life)
- Grease bearing. Follow manufacturer’s instructions!

**Belt Drive – Periodic Maintenance**
- Check belt drive for contamination, damage, wear, tension, alignment of motor and fan pulley (tolerance < 0.4°; d.h. < 7 mm/m), check function and fastening (see torque settings)
- Check protective device for damage, fastening and functioning

**Belt Drive – Maintenance when necessary**
- Replace belt set
- Adjust alignment of motor and fan pulley
- Adjust belt tension (see page 28)
- Clean belt drive

**Drive Clutch – Periodic Maintenance**
- Follow manufacturer’s instructions!
- Check drive clutch for function, contamination, damage, corrosion and fastening
- Check temperature

**Drive Clutch – Maintenance when necessary**
- Follow manufacturer’s instructions!
- Change oil
- Clean drive clutch

Motor Removal
When removing the motor only use suitable and permitted load bearing equipment. When using an integrated motor removal device ensure that the unit is sufficiently stable e.g. by fixing to the foundation.

Shut Down
Remove V-belts for down times of more than 3 months to avoid concentrated stress on bearings.
Replace bearings before recommissioning if out of operation for periods of one year or longer, or remove grease if bearings have a regreasing device and grease bearings again. Observe fan manufacturer’s instructions.

Determination of Belt Pretensioning Force for V-belts DIN 7753

Belt Tension
The belt tension is measured with a suitable measuring instrument in line with instructions (e.g. belt pretensioning force measuring instrument) and adjusted. Observe operating instructions for measurement instrument.
- Measure axle base A of the belt pulleys (in metres).
- Multiply axle base by 16. The result is the belt deflection (S) in millimetres.
- Apply enough force to the belt in the middle of the axle base (A) so that the calculated deflection is reached.
- Measure deflection force.
- Compare deflection force (F) with table values.

Set higher values for the start up phase of new drives. Test deflection force (F) after several hours of operation and adjust if necessary.

A – Axle base; S – Belt deflection; F – Deflection force
Note
For one-groove drives it is easier to use a ruler to set deflection.

The values shown below only apply to narrow V-belts DIN 7753. If other V-belts are used, the manufacturer should be consulted.

Force \((F)\) for Deflection \((S)\) = 16 mm per metre of axle base \((A)\)

Filters

Commissioning

**Caution**
Observe general safety instructions on page 3!

**Installation of Filter Cartridges**
- Carefully fix filter elements to the frames with tension springs or anchor wallers respectively, cartridge filters to be fastened to bayonet joints hand tight.
- Do not shut or damage filter cartridges.
- Check air proof seating of the filter cartridges in the frame.

Only use approved filter media with ATEX units.

**Filter Monitoring**
In order to check the degree of contamination of the filters (except activated carbon filters), the fitting of a differential pressure manometer on the access side of the unit is recommended.

**Final Pressure Drop Filter**
Recommended Final Pressure Drop for ISO 16890 Filters

### Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
Allergic reactions on the skin, eyes or breathing organs can be caused by contact with filter dusts. For maintenance and replacement works on filter cartridges wear protective clothing and, if necessary, a respirator. Avoid contamination of the surrounding area and new filters.

**Replacement Filters**
Keep at least one set of replacement filters in stock. Store in a dry and dust free area. Avoid contamination and damage. Do not use filters beyond minimum durability.

**Filter media with ATEX units.**

**Filters – Periodic Maintenance**
- Check filter cartridges for hygiene, contamination, odors, damage and corrosion
- Particle filters: Check differential pressure with manometer
- Activated carbon filters: Usually, it is enough to check the filter’s odor. (For a reliable determination of the remaining lifetime, the manufacturer may check the filter coal’s saturation in his lab in order to appoint proper service intervals.) Weighing of the cartridges does not deliver feasible results, since most of the additional weight is caused by the air’s humidity.
- Check filter seat for leakage

**Filters – Maintenance when necessary**
- Replace filter cartridges immediately if there is noticeable contamination, odor, damage or leakage, when reaching the recommended end resistance or time interval:
  1. Filter cartridge after 12 months at the latest
  2. Filter cartridge after 24 months at the latest

An earlier filter change may be essential if building or conversion measures result in significant strain on the filter or following a hygiene inspection.

The change of single filter elements is only permissible in the case of damage to individual elements provided that the last change does not date back more than 6 months.

When changing the filter cartridges observe the local environmental protection regulations.
Silencer

Commissioning

Caution
Observe general safety instructions on page 3!

Inspection
Check silencers for damage and contamination; for repair and cleaning see below.

Maintenance

Maintenance Interval
Every three months. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Silencer – Periodic Maintenance
- Check silencers for hygiene, contamination, damage and corrosion

Silencers – Maintenance when necessary
- Clean silencers (see below), repair them with repair kit and rectify corrosion; take contact samples if necessary

Cleaning
Use vacuum cleaner to clean surfaces.

Attention
Do not damage absorption material.
Heating Coil (Hot Water, Steam, RAC, HE-RAC)

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
Do not use any hot medium while filling, bleeding air or removing as there is a danger of scalding.

Caution
To avoid burns, do not touch hot surfaces.

Caution
Avoid any contact with brine while charging or venting. Danger of poisoning and acid burns! Observe manufacturer’s instructions.

Attention
Do not exceed permissible pressure range (see design data sheet).
To avoid freezing of the heating coil:
Add anti-freeze agent or install frost protection control on air, water or condensate side depending on unit design.

To avoid any overheating damage to the unit, run steam coil only when fan is running
Provide air flow control or temperature limiter.

Ensure sufficient distance between max. surface temperature of the heat exchanger due to temperature of the medium and minimum ignition temperature of any flammable mixture which may be present in accordance with EN 1127.

Inspection
Check inlet outlet connections for function (counter flow principle).

Charging
The system must be rinsed (removal of contaminations) according to VDI 2035 and should be filled with the heat exchanger fluid named in the design data sheet to the correct concentration. In case of no or only insufficient system flushing, residual oil can remain in the heat exchanger (lubrication during the production process). The residual oil must be dissolved during the flushing process, otherwise the oil is still in the system. Water / antifreeze mixtures have lipophilic properties and the oil is dissolved in the mixture. Subsequently, an oil / water / antifreeze mixture circulates in the system and damages seals that are not oil resistant. In closed system circuits (exp. runaround systems), the use of oil resistant seals is generally recommended.

Water quality to VDI 2035. Too high a concentration of glycol leads to reduced performance, too low a concentration of glycol can lead to frost damage.
Venting
When charging the system according to VDI 2035 the heating coil and the system should be vented carefully at the highest point of the system. For this purpose open the venting screw at the top connection or open separate venting screw. If incorrect venting takes place, heating coils develop air locks which lead to a reduction in capacity. Recommendation: Venting recovery system (stop-cock with hose nozzle).

After Commissioning
After commissioning check the screw fittings of the flange for leakage and retighten if necessary (see page 14).
Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
To avoid burns, do not touch hot surfaces.

**Caution**
Before starting work allow components to cool/warm up to the ambient temperature.

**Caution**
Avoid any contact with brine while charging or venting. Danger of poisoning and acid burns! Observe manufacturer’s instructions.

**Heating Coil – Periodic Maintenance**
- Check heating coil for hygiene, contamination on air side, damage, leaks and corrosion
- Vent heating coil
- Check inlet/outlet for function
- Check frost protection for function (determine anti-freeze concentration or thermostat by means of cooling spray)

**Heating Coil – Maintenance when necessary**
- Clean the heating coil on the air side (see below), rectify damage, leakage and corrosion

**Cleaning**
Clean coils already assembled or if not accessible pull them out for cleaning. Contamination which has been removed must not enter adjoining unit parts. Remove dirt and contaminated water carefully.

Observe the following points:
- Avoid bending plate fins
- Blow out with compressed air in the opposite direction
- Do not use a high pressure cleaner or a high pressure steam cleaner
- Clean with water and low pressure

**Cleaning Agents**
Use cleaning agents with a pH-value between 7 and 9 if required.

**Shut Down**
If out of operation for some time, especially if there is a danger of freezing, the heat exchanger must be emptied completely if no anti-freezing agent was added. For this purpose remove all purging and discharging screws. Then for complete emptying blow air (compressed air, fan etc) through each heat exchanger as up to 50% fluid may remain in the heat exchanger during free purging which results in a higher danger of damage during frost. Remove brine following manufacturer information.
**Removal / installation**

After decommissioning the heat exchanger and disassembling the control group, unscrew the front panel with Torx (T25) or flat-tip screwdriver. (Air cooler: Unscrew the condensate deflector plate from the housing frame.) Pull out the heat exchanger including the front panel to the front (support the heat exchanger if necessary). Check seals for damage and replace them if necessary. Installation has to be done in reverse order.
Electric Heater

Commissioning

**Caution**
Observe general safety instructions on page 3!

**Caution**
To avoid burns, do not touch hot surfaces.

**Ex**
Only use approved parts with ATEX units. All electrical parts must be earthed.

**Safety Temperature Limiter**
Each electric heater must be equipped with a fully tested safety temperature limiter with manual reset. Test function with hot air drier.

**Recommendation**
Triple thermostat mounted directly downstream from electric heater:
- “Fan” setting: 40 °C.
- “Safety temperature limiter” setting: 70 °C.

**Attention**
Electric heaters may only be operated if flow control is present. Overheating damage may occur to the electric heater, housing and other fitted parts if the system is run with insufficient cooling (e.g. system switched off at the main switch when the electric air heater is still on) or in the event of an emergency system shut down triggered by safety devices.

**Flow Control**
The airflow is monitored by measurement of the pressure difference at the fan unit, using an air pressure gauge Functioning must be checked during commissioning.

**Current Consumption**
The current consumption is to be checked at all phases by measuring all phases. For rated data see nameplate.
If the rated values are exceeded, the robatherm Technical Service must be informed.
Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
To avoid burns, do not touch hot surfaces.

**Caution**
Before starting work allow components to cool/warm up to the ambient temperature.

**Electric Heater – Periodic Maintenance**
- Check functioning of airflow control; for this remove pressure measurement tubes from air pressure gauge. A switching operation must take place
- Check electric heater for function, hygiene, contamination, damage, corrosion and fastening
- Check function of safety temperature limiter (see Commissioning)

**Electric Heater – Maintenance when necessary**
- Clean electric heater, rectify scaling, damage, corrosion, retighten fastenings
Cooling Coil (CW – DX Coil, RAC, HE-RAC)

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
Avoid any contact with brine while charging or venting. Danger of poisoning and acid burns!
Observe manufacturer’s instructions.

Caution
To avoid burns, do not touch hot/cold surfaces.

Attention
Do not exceed permissible pressure range.
To avoid freezing of the cooling coil:
Add anti-freeze agent or mount the cooling coil downstream from the pre-heater.

Inspection
Check inlet outlet connections for function (counter flow principle).
In the case of direct expansion coils, the nitrogen protection gas must escape with a hissing noise following opening of the heat exchanger connections. Otherwise there is a leakage; please inform our technical service.

Charging
The system must be rinsed (removal of contaminations) according to VDI 2035 and should be filled with the heat exchanger fluid named in the design data sheet to the correct concentration. In case of no or only insufficient system flushing, residual oil can remain in the heat exchanger (lubrication during the production process). The residual oil must be dissolved during the flushing process, otherwise the oil is still in the system. Water / antifreeze mixtures have lipophilic properties and the oil is dissolved in the mixture. Subsequently, an oil / water / antifreeze mixture circulates in the system and damages seals that are not oil resistant. In closed system circuits (exp. runaround systems), the use of oil resistant seals is generally recommended.
Water quality to VDI 2035. Too high a concentration of glycol leads to reduced performance, too low a concentration of glycol can lead to frost damage.

Venting
When charging the system according to VDI 2035 the air cooler and the system should be vented carefully at the highest point of the system. For this purpose open the venting screw at the top connection or open separate venting screw.
If incorrect venting takes place, cooling coils develop air locks which lead to a reduction in capacity. Recommendation: Venting recovery system (stop-cock with hose nozzle).

After Commissioning
After commissioning check the screw fittings of the flange for leakage and retighten if necessary (see page 14).
Maintenance

Maintenance Interval
Every three months. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Caution
Avoid any contact with brine while charging or venting. Danger of poisoning and acid burns!
Observe manufacturer’s instructions.

Caution
To avoid burns, do not touch hot/cold surfaces.

Caution
Before starting work allow components to cool/warm up to the ambient temperature.

Cooling Coil – Periodic Maintenance
- Check cooling coil for hygiene, contamination on air side, damage, leaks and corrosion
- Vent cooling coil
- Check drip pan for contamination, clean if necessary
- Check water outlet and siphon function, clean if necessary
- Check water level in siphon refill if necessary
- Check inlet / outlet for function
- Check frost protection for function (determine anti-freeze concentration or thermostat by means of cooling spray)
- Check direct expansion for icing

Cooling Coil – Maintenance when necessary
- Clean the cooling coil on the air side (see below), rectify damage, leakage and corrosion

Drop Eliminator – Periodic Maintenance
- Check drop eliminator for hygiene, contamination, encrustation, damage, drip erosion and corrosion

Drop Eliminator – Maintenance when necessary
- Clean and service eliminator: Pull out cassette, disassemble and clean profiles separately; rectify damage and corrosion

Cleaning
Clean heat exchangers already assembled or if not accessible pull them out for cleaning.
Contamination which has been removed must not enter adjoining unit parts. Remove dirt and contaminated water carefully.
Observe the following points:
- Avoid bending plate fins
- Blow out with compressed air in the opposite direction
- Do not use a high pressure cleaner or a high pressure steam cleaner
- Clean with water and low pressure
Cleaning Agents
Use cleaning agents with a pH-value between 7 and 9 if required.

Shut Down
If out of operation for some time, especially if there is a danger of freezing, the heat exchanger must be emptied completely if no anti-freezing agent was added. For this purpose remove all purging and discharging screws. Then for complete emptying blow air (compressed air, fan etc) through each heat exchanger as up to 50% fluid may remain in the heat exchanger during free purging which results in a higher danger of damage during frost. Remove brine following manufacturer information.

Removal / installation
After decommissioning the heat exchanger and disassembling the control group, unscrew the front panel with Torx (T25) or flat-tip screwdriver. (Air cooler: Unscrew the condensate deflector plate from the housing frame.) Pull out the heat exchanger including the front panel to the front (support the heat exchanger if necessary). Check seals for damage and replace them if necessary. Installation has to be done in reverse order.
Refrigeration Installations and Heat Pump

**Caution**
Observe general safety instructions on page 3!

**Caution**
Avoid any physical contact with the refrigerant as this may cause frostbite to the skin and limbs or retinal damage. Use personal protection equipment against effects of refrigerants BGV D4 (goggles, gloves, etc.)!

Refrigerant (odourless and tasteless) ejects atmospheric oxygen and can cause suffocation. TLV values (for R407C: 1,000 ppm in 8h) and practical value limit DIN 8960 (for R407C: 0.31 kg/m³ area) must be observed. If refrigerant does escape only enter the machine room with heavy duty respiratory protective gear. Observe the safety data sheet.

Refrigerants and compressor oil develop toxic, noxious substances in tandem with naked flame. Do not inhale! Do not smoke in the machine room!

There may be an allergic reaction if compressor oil is touched or swallowed. Avoid physical contact! Observe safety data sheet.

**Ex**
Only use approved parts with ATEX units. All electrical parts must be earthed.

**Attention**
Completion and commissioning of refrigeration installations may only be carried out by the manufacturer or another expert assigned by the manufacturer; maintenance and servicing work only by qualified personnel.

For all work the requirements of the service booklet (request if required), and the valid standards and guidelines (e.g. DIN EN 378, BGR 500 and EC-F Gas Directive) must be adhered to.

**Recurring Inspections**
According to §15 of the German Industrial Safety Regulation (BetrSichV), the units and unit parts underlie recurring inspections by an authorized person respectively accredited inspection agency. Further applicable statutory provisions of the respective location are to be observed.

**Commissioning Requirements**
All construction requirements such as access, completed unit and duct installation and uninterrupted availability of all supply facilities must be met. In addition there must be a possibility of operating the system in the required working phases.

**Basis for Warranty**
The basis for the warranty is built on a maintenance contract with a qualified company specialised in refrigeration engineering together with records of performance of maintenance work.
System Operation
Operation of the refrigeration unit is only permissible when the AHU is running. Breakdowns of faults of the refrigerating unit are displayed on the switch cabinet. According to the German Industrial Safety Regulation (BetrSichV), such units require special supervision; including specific operator-related requirements that are to be fulfilled according to §14 of the German Industrial Safety Regulation. Further applicable statutory provisions of the respective location are to be observed.

Maintenance and Inspection
For requirements see service booklet for refrigeration installations.

Recurring inspections
According to §15 of the German Ordinance on Industrial Safety and Health (BetrSichV), the system and the system components are subject to partially recurring inspections by a qualified person or authorized inspection body. Further applicable legal regulations of the respective country of installation have to be taken into consideration.

Attention
Only use oil approved by the compressor manufacturer (see information on the compressor) as there may otherwise be damage to the unit.

Shut Down
For requirements see service booklet for refrigeration installations.

Heed the relevant environmental regulations when disposing of refrigerant or compressor oil.
Rotary Heat Exchanger

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
When current feed is not disconnected at all poles, there is a risk of crushing and scraping to the limbs through sudden running of the rotor caused by an automatic cleaning run or automatic re-start after power failure.

Only use approved parts with ATEX units. All electrical parts must be earthed.

Inspection
Before commissioning ensure that no objects obstruct the free running of the rotor. Remove any foreign bodies and contamination.

Sealing Strips
Check contact pressure of sealing strips. They must be placed as close as possible to the thermal mass and direct dragging must be avoided even under operating pressure.

Bearing
In principle the bearing of the rotor is aligned in the factory. Depending on installation conditions some rework may be necessary. Please observe the manufacturer’s instructions.

Drive
Open inspection cover at marked rotor corner and check whether V-belt has enough tension from tensioning device, shorten V-belt if necessary:
- Open hinged lock
- Shorten endless belt as required
- Close hinged lock
- Close inspection cover

As the V-belt is subject to natural stretching, the tension of the V-belt should be regularly checked in the first 400 operating hours in particular.

Put drive motor into operation. For rotor controller observe the manufacturer’s operating instructions.
Check pre-defined rotor speed (e.g. 10 rpm for 10 V input signal).

Direction of Rotation
Check rotational direction of rotor (arrow), if necessary change electrical connections of motor. If a washing zone is installed the storage mass must turn from extract air via the washing chamber into the supply air.
**Pressure Drop**
In order to avoid contamination of the supply air with the extract air, the pressure potential of the fans should be selected in such a way that the system related leakage from the supply air side flows into the extract air side.

**Adiabatic Humidification of Extract Air**
Excessive humidity shall be avoided upstream of the rotor to prevent its matrix from over-wetting. If ever possible, permeate from the reverse osmosis should be used to operate the humidifier.

Zone crossing must be avoided with ATEX units in all circumstances.
Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
When current feed is not disconnected at all poles, there is a risk of crushing and scraping to the limbs through sudden running of the rotor caused by an automatic cleaning run or automatic re-start after power failure.

**Attention**
In order to avoid damage when cleaning, air or water jet should only be directed onto the surfaces of the heat exchanger at a right angle.

**Rotary Heat Exchanger – Periodic Maintenance**
- Check rotary heat exchanger for hygiene, foreign bodies, contamination, damage and corrosion
- Check sealing strips for contamination, foreign bodies and contact pressure (see above)
- Check drive belt for wear and tension, shorten (see above) or change if necessary
- Check rotor for imbalance and lateral trueness
- Check bearing for incorrect heating, vibrations or running noises and change if necessary (no later than the end of the theoretical service life)
- Check water outlet and siphon function clean if necessary
- Check water level of siphon, top up if necessary
- Check functioning of rotor control, align sensor if necessary

**Rotary Heat Exchanger – Maintenance when necessary**
- Rectify foreign bodies, contamination, damage and corrosion
- Clean rotor body with compressed air or high pressure cleaner (only water without additives); remove dirty water carefully
- Clean sealing strips, change if there is abrasion
- Adjust contact pressure of sealing strips (see above)
- Balance or align rotor

**Shut Down**
If rotor is out of action for a longer period (e.g. summer), turn it on intermittently to maintain self-cleaning function.
Plate Heat Exchangers

Commissioning

Caution
Observe general safety instructions on page 3!

Attention
In order to avoid damage to the heat exchanger, do not exceed the maximum permissible pressure drop SUPPLY/EXTRACT (depending on type approx. 1,000 Pa). Observe notes for closing dampers (see page 21)

Zone crossing must be avoided with ATEX units in all circumstances.

Inspection
Check (and clean if necessary) plate heat exchanger for foreign particles and contamination (see below).

Maintenance

Maintenance Interval
Every three months. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Attention
In order to avoid damage when cleaning, air or water jet should only be directed onto the surfaces of the heat exchanger at a right angle.

Plate Heat Exchanger – Periodic Maintenance
- Check plate heat exchanger for hygiene, foreign bodies, contamination, damage and corrosion
- Check water outlet and siphon function, clean if necessary
- Check water level of siphon, top up if necessary

Plate Heat Exchanger – Maintenance when necessary
- Rectify foreign bodies, contamination, damage and corrosion
- Clean with compressed air or high pressure cleaner (only water without additives); remove dirty water carefully
Heat Pipe

Commissioning

Caution
Observe general safety instructions on page 3!

Inspection
Check (and clean if necessary) heat pipe for foreign particles and contamination (see below).

Maintenance

Maintenance Interval
Every three months. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Caution
There is a danger to life when charging gas under high pressure! Do not damage or overheat pipes (e.g. by means of welding torch).

Heat Pipe-HRS – Periodic Maintenance
- Check heat pipe for hygiene, contamination, damage and corrosion
- Check water outlet and siphon function, clean if necessary
- Check water level of siphon, top up if necessary

Heat Pipe-HRS – Maintenance when necessary
- Clean the heat pipe on the air side (see below), rectify damage and corrosion

Cleaning
Observe the following points:
- Avoid bending plate fins.
- Blow out with compressed air in the opposite direction.
- Do not use a high pressure cleaner or a high pressure steam cleaner.
- Clean with water and low pressure.

Cleaning Agents
Use cleaning agents with a pH-value between 7 and 9 if required.
Desiccant Rotor

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
When current feed is not disconnected at all poles, there is a risk of crushing and scraping to the limbs through sudden running of the rotor caused by an automatic cleaning run or automatic re-start after power failure.

Attention
If commissioning is not undertaken correctly, overheating, frost damage, erosions of the rotor body or odor problems may occur depending on the type of rotor. It is compulsory to observe the rotor manufacturer’s information (request if necessary)! Do not operate LICI-rotors with e.g. supersaturated air or clean wet.

The commissioning must be carried out in accordance with the rotor manufacturer’s instructions and the commissioning described by robatherm (see page 44).

Rotor Speed
The desiccant rotor requires a much lower speed during dehumidification than during HRS operation. The defined rotor speeds have to be checked, e.g. during dehumidification 10 l/h for 2 V input signal (or the priority contact is closed) and in HRS operation 10 l/min for 10 V input signal.

Pressure Drop
In order to avoid contamination of the supply air with the humid regeneration air, the pressure potential of the fans should be selected in such a way that the system related leakage from the supply air side flows into the regeneration air side.

Zone crossing must be avoided with ATEX units in all circumstances.
Maintenance

**Maintenance Interval**
Every three months. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

**Caution**
When current feed is not disconnected at all poles, there is a risk of crushing and scraping to the limbs through sudden running of the rotor caused by an automatic cleaning run or automatic re-start after power failure.

**Maintenance Work**
The maintenance work must be carried out in line with the instructions of the rotor manufacturer (ask if required).

**Desiccant Rotor HRS – Periodic Maintenance**
- Check rotor for hygiene, foreign bodies, contamination, damage and corrosion
- Check sealing strips for contamination, foreign bodies and contact pressure (see above)
- Check drive belt for wear and tension, shorten (see above) or change if necessary
- Check rotor for imbalance and lateral trueness
- Check bearing for incorrect heating, vibration or running noises and change if necessary (no later than the end of the theoretical service life)
- Check functioning of rotor control, align sensor if necessary

**Desiccant Rotor HRS – Maintenance when necessary**
- Rectify foreign bodies, contamination, damage and corrosion
- Clean body of rotor in line with rotor manufacturer's instructions. Depending on the rotor type, wet cleaning may lead to the destruction of the rotor!
- Clean sealing strips, change if there is abrasion
- Adjust contact pressure of sealing strips (see above)
- Balance or align rotor

**Shut Down**
If standstill is for a longer period, put the rotor intermittently into operation in line with the manufacturer's instructions to maintain self purification of the rotor.
Combustion Chamber

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
To avoid burns, do not touch hot surfaces.

Caution
Observe requirements in line with DIN 4794, DIN 4755 and DVGW-worksheet (German Technical and Scientific Association for Gas and Water) G600. There is a danger of fire if flammable materials come into contact with the combustion chamber.

Operation in explosion hazard zones not permitted. Flush to ensure that no explosive atmosphere is present before the burner ignites.

Attention
First commissioning of a combustion chamber or the associated system must be carried out by the manufacturer or a specialist appointed by the manufacturer following DIN 4794.

Flame Pot (refers to RWE substitute combustion chamber)
Check position of flame pot; it must be positioned vertically by the back wall.

Emission values
- Nominal flue gas temperature: approx. 170-190 °C at nominal capacity for condensate combustion chambers.
- Minimum flue gas temperature: approx. 120 °C for combustion chambers of the RWE series.

Connection
In the case of customer-supplied burners, approval by robatherm must be requested for compatibility testing with the selected combustion chamber. Installation of oil or gas burner in accordance with manufacturer's instructions. Connect burner to oil or gas line. The operating instructions of the oil or gas burner manufacturer must be followed exactly.
Install and wire all sensors and thermostats.
Attention
Every system must be equipped with an emergency switch. Overheating damage of combustion chamber, casing, components etc. may occur when the unit is operated with insufficient cooling (e.g. the unit is switched off via crash switch and burner is still running) or the units are switched off via safety bodies. There is a danger of fire if flammable materials come into contact with the combustion chamber. Check that there is a good distribution of the airflow at the inlet and outlet of the combustion chamber!

Combustion Air
The required combustion air (environmentally compatible) amounts to approx 1 m³/h per kW installed burner capacity. The intakes should be designed inside the building following TRGI, in the unit to a max. of 1 m/s, min. 150 cm².

Chimney
Make connection to chimney in accordance with applicable regulations. The exhaust system must meet the civil engineering and official regulations.

Readiness for Operation
Combustion Chambers oft he RWE series
Make ready for operation:
- Vent oil or gas line.
- Check adjustment values of the triple thermostat:
  - Burner: approx. 70 °C
  - Fan: approx. 40 °C
  - Position of sensor approx. 10 cm downstream from combustion chamber
- For 2 stage burner check set values of single thermostat: approx. 60 °C.

Condensate Combustion Chamber
- Follow the instructions oft the sobustion chamber supplier. These are part of the documentation supplied.

Gas Consumption
Gas consumption depends on the operating point and the power output. It can be estimated using the equation:
Gas consumption (G20, standard-m³/h) = 0,11 x power (kW)
For more detailed information, refer to the manufacturer documentation.

Burner
Put burner into operation. The commissioning instructions of the burner manufacturer must be followed precisely. Please ensure that the fan is in constant operation. The fuel supply must be set in such a way that the rated capacity QN is not exceeded. For this it is essential to use a gas meter for a gas burner.

Check the flame; it must not touch the combustion chamber walls. Use flame head extension or other nozzle angle.
Control and Safety Bodies
Check triple thermostat:
- The fan should start at set “fan” value = 40 °C. Functional test by means of e.g. hot air drier.
- The burner should switch off at set “burner” value = 70 °C. Functional test by means of e.g. hot air drier.
- For functional test of the safety temperature limiter, heat the capillary by means of hot air drier for example. Burner must switch off at approx. 100 °C and the safety temperature limiter must lock. If this does not happen automatically, stop burner, replace triple thermostat and repeat whole test.
- Unlock safety temperature limiter manually by reset button.

The single thermostat is to be tested in the same way as the triple thermostat. The second burner stage must be switched on or off at approx. 60 °C.

Damper Regulation
For combustion chambers with bypass, the active direction of the dampers must be checked. If necessary reverse direction of rotation of servo motor by adjusting the slide switch. For further information see page 21.

Combustion chamber temperature regulation:
- If the heating requirement increases, the combustion chamber damper must open and the bypass damper close. The dampers do the opposite when there is a reduced heating requirement.
- In order to guarantee adequate cooling of the combustion chamber, the combustion chamber damper may be closed no further than 10 mm of free opening cross section between the damper blades. Provide a limit switch to switch off the burner.

Temperature control of flue gas:
- When under-running the set minimum temperature of the flue gas the combustion chamber damper (if present) must close and the bypass damper must open. When the set flue gas maximum temperature is exceeded, the burner capacity must be reduced.

Emission Values
Establish emission value following DIN 4794.

Combustion Chambers oft he RWE series
- Maximum emission temperature: approx. 210 °C (protection regulations, observe newest version).
- Minimum emission temperature: approx. 150 °C (to reduce formation of condensate). Observe minimum operation time of burner.

All settings must be documented and filed in the setting records.

Condensate Combustion Chamber
- At maximum power output 175-192 °C (depending on model)

Condensate
Condensate piping must be professionally connected and incidental condensate must be disposed of in line with the local regulations (e.g. ATV information sheet).

Condensate Quantity
The amount of condensate accuring depends on the mode of operation and power output. It can be estimated using the equation:
Condensate quantity (kg/h) = 0,10 x power (kW)
Maintenance

Maintenance Interval
One shift operation: Min. 1 x per year
Two shift operation: Min. 2 x per year
Three shift operation or other modes of operation: Min. 3 x per year

Caution
Observe general safety instructions on page 3!

Caution
To avoid burns, do not touch hot surfaces.

Caution
Before starting work allow components to cool/warm up to the ambient temperature.

Caution
Observe requirements in line to DIN 4794, DIN 4755 and DVGW-worksheet (German Technical and Scientific Association for Gas and Water) G600.
When working on the flame pot, wear protective clothing (skin, eye and inhalation protection). Observe safety data sheet (ask if required). There is a danger of fire if flammable materials come into contact with the combustion chamber.

Combustion Chamber – Periodic Maintenance
- Dismantle burner. Check combustion chamber for contamination, damage and leaks. If damage or leaks are found the manufacturer must be informed immediately in order to effect appropriate repairs. The burner may not be operated until the damage is rectified.

Combustion Chamber – Maintenance when necessary
- Following cleaning of the ancillary surface, vacuum the combustion chamber if necessary.

Flame Pot – Periodic Maintenance
- Check flame pot for damage. Slight cracking is normal. Replace if there is damage or deformation or after 5,000 operating hours. To do this remove burner plate and cylinder cover.

Reheating Surface – Periodic Maintenance
- Remove inspection cover and cleaning cover of the combustion chamber. Remove all turbulators and check for general condition. Replace if there is heavy corrosion.
- Check drainage device and clean if necessary.

Reheating Surface – Maintenance when necessary
- Clean all reheating surface pipes with a stainless steel brush and vacuum the collector.

Burner – Periodic Maintenance
- On completion of combustion chamber cleaning, the burner maintenance is to be carried out in accordance with the instructions of the burner manufacturer (in line with DIN 4755 or DVGW-worksheet G600).
- Establish exhaust gas values as per Federal Emissions Protection Act.
- A record is to be established of all work and forwarded to the manufacturer automatically.
- Check gas pipes, connections and gas control system for leaks and eliminate any leaks found.
Control and Safety Bodies – Periodic Maintenance
- Inspection according to commissioning.

Bypass- and Combustion Chamber Damper – Periodic Maintenance
- For maintenance see chapter "dampers".
- Checking of active direction: See commissioning.

In general the chimney sweep is responsible for the maintenance of the exhaust pipe (chimney).

Condensate Combustion Chamber
- Follow the instructions oft the sobustion chamber supplier. These are part of the documentation supplied.

In general the chimney sweep is responsible for the maintenance of the exhaust pipe (chimney).
Gas Surface Burner

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
The CO₂ concentration of the indoor air must not exceed locally prescribed value limits! Recirculation air operation is not permissible! Do not enter running unit due to danger of burns.

Operation in explosion hazard zones not permitted. Flush to ensure that no explosive atmosphere is present before the burner ignites.

Attention
First commissioning of a gas surface burner or the associated system must be carried out by the manufacturer or a specialist appointed by the manufacturer following DIN 4794. This person must be approved by the DVGW as a gas expert. There is a danger of fire if flammable materials come into contact with the flame.

Regulations
When the unit is installed, the points here must be followed together with any conditions imposed by the certifying authority, all local regulations and the DVGW and TRGI requirements must be adhered to precisely.

Connections
Connect controlled gas system to the gas pipe. Ensure that there is no stress on connections. Type of gas and gas pressure must be suitable for the control system. Install blow valve outside the building. Install and wire all sensors and thermostats (room thermostats etc.).

Leak Test
Check gas pipe, connections and gas control system for leaks via testing instrument.

Attention
Every system must be equipped with an emergency switch. Overheating damage of combustion chamber, casing, components etc. may occur when the unit is operated with insufficient cooling (e.g. the unit is switched off via crash switch and burner is still running) or the units are switched off via safety bodies. There is a danger of fire if flammable materials come into contact with the combustion chamber. Check that there is a good distribution of the airflow at the inlet and outlet of the combustion chamber!

Readiness for Operation
Make ready for operation:
- Vent gas line.
- Check setting of limit value of safety temperature limiter: 60 °C as standard. Suction and blow openings must be open during operation.
Burner
Put burner into operation. Observe continuous operation of supply and extract fan without any recirculation air.
This work is only to be performed by the robatherm customer service unless an alternative agreement has been made.
The numbers shown below refer to the figures on page 60:
- Open stopcock (1), check pressure at manometer (11). It must correspond to the rated pressure in accordance with nameplate.
- Set gas pressure gauge min (9) at lowest value.
- Set gas pressure gauge max (10) at highest value.
- Set air pressure gauge on burner panel at lowest value.
- For units with combustion air blower: Set air pressure gauge of supporting blower at lowest value.
- Set desired value of duct and room sensor and thermostats above the respective ambient temperature.
- Set control switch on switch cabinet to “heating”.

Unit will now start burner.
If there is a fault shutdown repeat start up several times (remaining air).

If there is no flame although there is gas at the burner:
- Check correct venting of the gas pipe.
- Check control units (6, 9, 10, 15, 16) electrically.
- Check fine wire fuse of control unit.
- Check electrical wiring in the switch cabinet and wiring of field units, correct if necessary.
- Check ignition electrodes.

If there is only a short flame although there is gas at the burner:
- Check UV diode for correct connection and discolouring, replace if necessary.
- For units with ionisation control: Check ionisation rod. Where appropriate remove contamination. Rod may not have any contact with metal parts. Check insulation body.
- For units with combustion air blowers check direction of rotation of the ventilator and reverse electrical connections if necessary.

Commissioning and Maintenance Work
The points listed below must also be included in maintenance work.

For testing of the safety temperature limiter (STL), heat the capillary by means of hot air drier for example. Burner must switch off at set value limit and the safety temperature limiter must lock. If this does not happen automatically, stop burner, replace STL and repeat whole test.
Unlock safety temperature limiter manually by reset button.

Check whether defined nominal airflow is set; adjust if necessary.

Adjust gas supply with on site gas meter by turning the setting screw on the pressure regulator (3) (control damper with servo motor (7) must be fully open).

At full load (control damper (7) fully open) the pressure on the manometer must match the rated pressure as per nameplate.

The rated value of the duct sensors or room sensor must be set lower than actual value. Control damper (7) must close.
Set minimum gas throughput using control damper (7). For this set control signal to 0 % and to smallest possible throughput by means of limit switch in actuator at which a homogeneous flame pattern is still available. Check via sight glass.

Set unit back to max. capacity (open control damper (7)).

Turn down gas pressure gauge max. (10) until it switches off.
Set value: Switch off value + approx. 20 %

Gas pressure gauge min. (9) remains at lowest setting.

Check direction of rotation of servo motor (7). If the room sensor is set above $t_{\text{set}}$, the servo motor (7) must open the control damper and vice versa.

Test the function of the controls.

Set sensors and thermostats to rated value.

The whole gas piping must be checked carefully for leakages with a leak indicator spray. If leakages are found, undertake appropriate repair work.

For units with combustion air blower, set combustion air pressure by adjusting suction restrictor; instructions of burner manufacturer must be followed exactly.
Set air pressure gauge on combustion air blower:
Set value: Switch off value – 20 %

Setting of burner slit: Nominal pressure loss at burner slit should be approx. 180 to 250 Pa.
Set pressure switch on burner slit:
Set value: Nominal pressure drop at burner slit – 40 %

All settings must be documented and filed in the setting records.
Maintenance

Maintenance Interval
One shift operation: Min. 1 x per year
Two shift operation: Min. 2 x per year
Three shift operation or other modes of operation: Min. 3 x per year

Caution
Observe general safety instructions on page 3!

Caution
Do not enter running unit due to danger of burns.
There is a danger of fire if flammable materials come into contact with the flame.

Gas Surface Burner – Periodic Maintenance
- Check gas pipes, connections and gas control system for leaks and eliminate any leaks found.
- All maintenance work must be performed as shown for commissioning.
- Clean off dirt with a brush; ensure that all air holes are clear. Check gas outlets, clean with injector needle if necessary. Do not touch with ignition electrode or controls.
- Check distance of the ignition electrodes; adjust if necessary.
For UV monitoring:
- Unscrew UV cell. Clean with soft cloth, refit. Change if discoloured.
For ionisation monitoring:
- Unscrew ionisation rod, clean with soft cloth, refit.

Gas Surface Cleaner – Maintenance when necessary
- The exchange of defective parts should only be carried out by a specialist in accordance with the procedure described (see page 56). Spare parts must be appropriate for the unit!

Spray Humidifier

Quality of Fresh and Recirculating Water

Before commissioning the quality of fresh and recirculating water must be checked.

Fresh Water

- Analysis of fresh water (usually available from local water authority).
- Total water hardness under 7° dH.
- Water quality following VDI 6022, VDI 3803, DIN EN 13053 and Drinking Water Ordinance

Recirculating Water

Limits for quality of recirculating water (recommendation partly based on VDI 3803 and German Printing Trades Association):

</table>

CBU = Colony Building Units

*) Descaling and part desalination may be necessary; for moistening above 95% r.h. electrical conductivity max 800 µS/cm.

**) Full desalination necessary

***) Lower value without extra measures for sterilisation; upper value with extra measures

Thickening Count

Establishment of thickening count from the values of the fresh water analysis and the recommended value limits for the quality of recirculating water (see table):

Thickening count – recommended value for recirculating water / value for fresh water.

Whereby the thickening count must be calculated for the electrical conductivity, hardness, chloride content and sulphate content. The lowest value of the calculated thickening counts should be close to the recommended value limits (see table). For values below 2, additional measures for water treatment should be taken. Contact a company specialising in water processing.
### Set Value
Setting values for hygienic monitoring can be established from the lowest thickening count:

\[
\text{Value limit for electrical conductivity} = \text{Lowest thickening count} \times \text{electrical conductivity of fresh water} \\
\text{(Rated value for blow down device or for monitoring with HYGIENECONTROL)}
\]

\[
\text{Cleaning interval} = \frac{\text{Sump capacity} \times (\text{thickening count} - 1)}{\text{evaporated water quantity}} \\
\text{(Setting value for time clock of HYGIENECONTROL)}
\]

**Note**
These settings values are approximations and do not replace the additional monitoring of germ counts.
We recommend the use of test systems (Dip-Slides). Follow instructions for use.

### Fresh Water Pressure
The ball valve is acceptable up to an operating pressure of max. 6 bar.
We recommend a fresh water pressure of at least 3 bar; if necessary install booster system.

### Adiabatic Humidification of Extract Air
Excessive humidity shall be avoided upstream of the rotor to prevent its matrix from over-wetting. If ever possible, permeate from the reverse osmosis should be used to operate the humidifier.
Commissioning

Caution
Observe general safety instructions on page 3!

Only use approved parts with ATEX units. All electrical parts must be earthed.

Cleaning
Clean foreign bodies out of humidifier sump, clean contamination with water and cleaning agent (non-foaming, pH-value 7 - 9).

Note
Remove swarf thoroughly, otherwise there is a risk of pitting!

Filling
Fill humidifier sump up to 10 to 20 mm below the overflow connector and set ball valve at this level by adjusting the knurled screw.

Note
When operating the spray humidifier there must be an airflow of at least 1 m/s (related to inside cross section of casing) against the spraying direction in order to avoid rectifier breakdown.
Treated water must be removed from galvanized parts immediately. White rust formation!

Pump
Put pump into operation. Follow instructions of the pump manufacturer.

Attention
Pump may only be operated if the sump is sufficiently filled.
Check pump direction of rotation, if it is incorrect swap electrical connections.

Dry Running Protection
Set dry running protection. The pump must switch off when the water level drops below 20 mm over the suction line, otherwise pull floating switch cables in or out as required.

Ball Valve
Check ball valve. At a maximum water level 10 to 20 mm below the overflow connector the fresh water supply must switch off.

Adjustability
For adjustable humidifiers the pump must switch off at a nozzle pressure of less than 0.3 bar. Setting of control valve or frequency converter as per manufacturer’s operating instructions.

Shut Down
The humidifier must be switched off automatically as soon as the AHU is switched off or fails.
Leak Testing
Test external piping for leakage, tighten if necessary.
Brand new eliminator profiles do not reach their full elimination capacity until approx 3 operating days have passed (weathering effect).

Hygiene Control
Sedimentation device: Adjust rated value for conductivity in accordance with manufacturer’s operating instructions (see page 62).

HYGIENECONTROL: Setting of the cleaning interval (see page 62) and value limit of the conductivity control.

Disinfection
UV rays (with self-controlling UV selective sensors) may be appropriate for continuous disinfection.
Only use chemical disinfection agents (biocides) if their harmlessness to health in the application concentration is proven.

Following commissioning the germ count of recirculating water should be checked on a weekly basis for a while. If necessary the setting values of the hygiene control may be adjusted.

Caution
Increased quantities of germs can cause infections or allergic reactions. If germ counts are over the recommended limits, clean or service system immediately. If in doubt or if germ counts again rise rapidly, you are recommended to have examination and advice from a qualified body.
If the results are below limits (see page 62), then see maintenance.
Maintenance

Caution
Observe general safety instructions on page 3!

Maintenance Work
Only fill the humidifier sump with fresh water if humidifying is required. The humidifier sump must be cleaned and dried when it is not operating and for standstill of over 48 hours.

Spray Humidifier – Weekly Maintenance*
- Empty humidifier sump and clean with fresh water**

Spray Humidifier – Two Weekly Maintenance*
- Check germ count of recirculating water and compare with permissible values (see page 62). If recommended germ count is exceeded, clean and disinfect immediately***.
- Examine inner surface for visible or tangible biological film (slimy covering), contamination, germs, damage or corrosion; if necessary service, scrub manually with a high pressure cleaner and disinfect***. If there are deposits through scaling then the recirculating water must have a commercially available descaling agent ***mixed into it; with the fan at a standstill, it must be allowed to take effect for several hours, the sump must then be emptied and cleaned with fresh water. If necessary remove drop eliminator and straightener profiles for cleaning.

Spray Humidifier – Half Yearly Maintenance
- Check mudflap, pump and pipes for dirt, coating, condition and function; if necessary clean with fresh water; if necessary service
- Check pump incl. bearings for quiet, vibration free running, heating and noises; perform corrective maintenance if necessary
- Check proper functioning of and clean the conductivity electrodes in line with manufacturer’s information, service if necessary
- Unscrew caps of atomizer nozzles and examine for deposits, clean with commercially available descaling agent*** if necessary
- Check dry running protection and ball valve and adjust if necessary (see page 64)
- Check function of the deconcentration device, water conditioning, sterilisation plant, water drain and overflow; service if necessary.
- Check shut off installations for function; service and adjust if necessary

Spray Humidifier – Maintenance when necessary
- Drying by fan slow down **
- Lubricate pump motor bearings in line with manufacturer’s instructions. Replace bearings (no later than the end of the theoretical service life)
- If the water conditioning or sterilisation plant breaks down all unit parts must be cleaned.
- Refill the humidifier sump with fresh water**

*) Quarterly maintenance for extract air humidifiers that do not influence the ventilation air quality.
**) Is performed automatically in units with HYGIENECONTROL, depending on the cleaning interval.
***) Observe manufacturer’s instructions.
Note
Treated water must be removed from galvanized parts immediately. White rust formation!

Shut Down
- Humidifier sump, siphon and pump (with drain plug or valve) should be completely drained.
- Remove drop eliminator and straightener profiles for cleaning.
- Clean spray humidifier completely with commercially available cleaning agents, if necessary descalers (follow manufacturer’s instructions).
- Dry inner surfaces by fan slow down.
- Do not refill humidifier sump until humidification is needed.
Description

Equipment depending on scope of customer order:

1 Drainage
2 Overflow with external siphon
3 Rapid filling
4 Manual cleaning
5 Floating valve
6 Cleaning nozzle bank
6.2 Cleaning nozzle bank 2 (≥T33)
7 Pump dry-run protection
8 Suction basket
9 Level control
10 Immersion heater
11 PTC Thermistor
12 Drain plug or valve
13 Drain plug of drip pan
14 Conductivity electrode
15 Straightener
16 Drop eliminator
17 Nozzle bank with vaporizer nozzle

Note
Drinking water connections shall be equipped with pipe isolators according to EN 1717.

Connect discharge (1) and outflow of the front sump (13) separately to the waste system. Do not discharge humidifier into the casing sloping pan!
High Pressure Spray Humidifier

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
For further information the individual commissioning instructions must be observed!

Only use approved parts with ATEX units. All electrical parts must be earthed.

Fresh Water
- Completely desalinated water (permeate from reverse osmosis) with max. 20 µS/cm and total water hardness max. 1 °dH.
- Water quality following VDI 6022, VDI 3803, DIN EN 13053 and Drinking Water Ordinance
- Water supply pressure: 2 to 8 bar
- Drinking water connections shall be equipped with pipe isolators according to EN 1717.

High Pressure Connection
- Check that high pressure hose is routed so that it is not subject to stretching or chafing; correct if necessary.
- Check threaded connections to humidifier and pump station for leaks; tighten if necessary. Use a second wrench for counter tightening.
- Internal bolts must not be retightened.

Pump Station
- Check oil level through sight glass or with a dipstick; if necessary top up with required type of oil (see information on pump station).
- Check tension of drive belt; retension with pulley if necessary.
- Check discharging screw for leaks; retighten if necessary. For this use a second wrench to counter turn.
- Set system in motion manually and check basic functions.
- Check pump direction of rotation, if it is incorrect swap electrical connections.
- Check protective devices as instructed.

Control Unit
- Commission control unit as instructed.
Maintenance

Maintenance Interval
See table.

Caution
Observe general safety instructions on page 3!

Caution
For further information the individual maintenance instructions must be observed!

High Pressure Spray Humidifier – Bi-weekly Maintenance
- Check pump station, hose connections, grating, nozzle blocks and nozzles, drop eliminators, humidifier pan and casing sides for function, foreign bodies, contamination, damage and corrosion; clean and service if necessary*
- Check for bacterial contamination of the humidifier pan floor, clean and disinfect if necessary.
- Check oil level; if necessary top up or change oil*
- Manually reverse filter element*

High Pressure Spray Humidifier – Half Yearly Maintenance
- Check shut off installations for function; service and adjust if necessary

High Pressure Spray Humidifier – Maintenance when necessary
- Replace wearing parts*

*) Observe manufacturer’s instructions

Note
Treated water must be removed from galvanised parts immediately. White rust formation!

Shut Down
Empty and dry out all water filled parts.
Clean entire spray humidifier (observe manufacturer’s information).
Electric-Steam Humidifier

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
In particular, the manufacturer’s operating instructions are to be observed!

Only use approved parts with ATEX units. All electrical parts must be earthed.

Requirements for Assembly / Installation

Steam generator
- Please observe the necessary minimum wall clearances
- The permissible ambient temperature is -5°C to 40°C.
  - If necessary, aeration (for installations in closed spaces) and/or frost control must be provided for.
- The device must be mounted plumb, both vertically and horizontally.
- Please take into consideration that the generator’s back wall can heat up to 70°C.
- May not be installed in rooms with negative pressure.

Hose System
- Hoses should be installed with a constant incline resp. constant decline of 5-10%.
- Any sagging or kinking of the hoses must be avoided.
- Steam hoses should be as short as possible.
  - To minimize condensate loss, insulation of the steam hoses is recommended for lengths > 5 meters.
  - Fixed piping is recommended.
  - Insulation is mandatory for lengths greater than 10 meters.
- Observe the minimum bending radius/radii.
- Depending on the installation position of the steam distributor and steam generator, the types of condensate hose guide installation must be observed.
- Condensate hose must be laid with a loop as a vapor barrier.

Steam distributors / Steam lances
- All steam distributors must be mounted horizontally.
- Installation as close to the steam generator as possible.
  - In this manner, steam losses thru condensate can be minimized.
- Preferred pressure-sided alignment with max. 1200 Pa excess pressure.
  - With suction-sided alignment max. -500 Pa.
- Max. Flow velocity: 3 m/s.
Hygrostat
- If the hygrostat is unfavorably positioned, exceedance of the maximum necessary steam output can take place.
- This could result in fact that subsequent components become soaked.
- As a guide: The distance of the hygrostat should be at least five times longer than the length of the humidification distance. The largest possible distance should be strived for.
- Check the hygrostat's function.

Requirements for Fresh Water Quality
- Use feed water without chemical additives.
- Max. 40°C.
- Permissible water supply pressure 1 up to 10 bar.
- Please observe the manufacturer’s instructions found in their operation manuals.
- The limits concerning electrical conductivity must be observed.

Requirement for the water supply and water drainage
- Local regulations of the waterworks or utilities must be observed.
- If not included in robatherm’s scope of supply, a system separator according to DIN EN 1717 must reliably prevent any backflow of water into the drinking water network.
- In accordance with DIN EN 1717, free flowage is required.
  - Attention: Danger of scalding by water temperatures up to 95 °C.

Requirements for the electrical connections
- All electrical work may only be carried out by qualified personnel.
- The connection may only take place after completion of all installation work.
- Please observe the corresponding information in the manufacturer’s operating manuals.

Attention:
The information compiled here is only part of the manufacturer's defined requirements and is intended to give an overview of the most important requirements. Careful consideration of the manufacturer’s operating manuals is mandatory.
Maintenance

Maintenance Interval
The required maintenance intervals essentially depend on the available water quality and the amount of generated steam.

Caution
Observe general safety instructions on page 3!

Caution
For further information, please consult the manufacturer's individual maintenance manual.

Typical maintenance intervals are listed as follows:

Steam humidifier - 4 weeks after commissioning
- Visual inspection of all joints and connections
- Clean steam cylinder, pump and hoses
- If necessary, Check electrode length
- Tighten all screws.

Steam humidifier - every six months
- Visual inspection of all joints and connections
- Clean steam cylinder, pump and hoses
- If necessary, Check electrode length
- Tighten all screws.

Please observe the manufacturer’s information.

Decommissioning
Please observe the manufacturer’s information.
Pressure Relief Damper

Commissioning

**Caution**
Observe general safety instructions on page 3!

**Caution**
There is a possibility of damage to persons or property as a result of impact or air jet under high pressure through unexpected release of the pressure relief damper!
Protective devices must be fitted and effective in accordance with DIN EN ISO 12100.

**Setting**
The release or application pressure of the pressure relief damper against the unit or duct wall can be varied by height adjustment, and altering the number and distance of weights (see characteristics).
The presetting is made by means of the indicated a-dimension.

By simulating maximum pressure in the network by using dampers which are as a rule present in every system, release pressure must be tested and weights adjusted if necessary.

**Caution**
Damage to persons or property may occur if the maximum pressure for the system is exceeded!
Characteristic Release and Application Pressure

A  Release pressure (Pa)
B  Number of weight plates (pcs)
C  a-distances (mm)

Maintenance

Maintenance Interval
Every year. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Pressure Relief Damper – Periodic Maintenance
- Check pressure relief damper for function, foreign bodies, contamination, damage and corrosion
- Treat all moving parts with lubricating and preserving spray
- Treat sealing with Vaseline
- Check release pressure, adjust if necessary.

Pressure Relief Damper – Maintenance when necessary
- Clean pressure relief damper and rectify any damage and corrosion
- Clean with a wet cloth, use grease or oil dissolving agents if necessary
Controlling Systems

Commissioning

Caution
Observe general safety instructions on page 3!

Only use approved parts with ATEX units. All electrical parts must be earthed.

Requirements
All construction requirements such as access, completed unit and duct installation and uninterrupted availability of all supply facilities must be met. In addition there must be a possibility of operating the system in the required working phases.
The commissioning may only be undertaken by a qualified company which specialises in process measurement and control technology.
At the start of the commissioning work, the commissioning engineer will be shown the system specific locations by a person nominated by the customer.

Work
The following work must be carried out:
• Check correct installation of the field units
• Check the electrical connections on the switchgear cabinet and the field units
• Functional test of sensors, transducers and actuators included in the supply package
• Configuration of control and/or DDC substations including loading of project specific control and SPS programmes
• Commissioning with all connected data stations
• Adjustment of the parameters to the operating conditions of the technical system, setting and regulation to the specified rated values and reference variables
• Testing of the control programmes
• Briefing nominated operating staff during the course of commissioning work
**Maintenance**

**Maintenance Staff**
Maintenance work must only be carried out by a qualified expert.

**Maintenance Contract**
A maintenance contract with a company which specializes in process measuring and control technology is recommended.

**Maintenance Interval**
Every year. ATEX units every month.

**Caution**
Observe general safety instructions on page 3!

---

**Switch Cabinets, Control Panels, controls – Periodic Maintenance**
- Check for proper and functionally correct installation and ambient conditions
- Check for contamination, corrosion and damage
- Check protective coverings are complete
- Check electrical/mechanical function of the connections, especially protective conductors
- Check functional elements (e.g. operating - and display devices)
- Check input signals (e.g. sensor, reference variable) match with rated value
- Check optical and acoustic control devices
- Check contactors and relays for wear and damage (e.g. contact erosion)
- Check switching and control processes (e.g. anti-freeze function)
- Check safety devices (e.g. thermal trips)
- Check setting of switch cabinet components (e.g. time relays)
- Check manual, automatic and remote control functions
- Change switch cabinet filter

**Switch Cabinets, Control Panels, Controls – Maintenance as required**
- Clean to maintain functioning
- Set, adjust, tighten functional elements (e.g. operating and display devices)
- Compensate signals
- Readjust

**Transducers, Safety and Monitoring Equipment, – Periodic Maintenance**
- Check for proper and functionally correct installation and ambient conditions
- Check for contamination, corrosion and damage
- Check electrical/mechanical function of the connections, especially protective conductors
- Measure and record measurable quantities at measurement point
- Check electrical, electronic and pneumatic measurement signals

**Transducers, Safety and Monitoring Equipment – Maintenance as required**
- Clean to maintain functioning
- Readjust, regenerate
### Controllers and Supplementary Modules – Periodic Maintenance
- Check for proper and functionally correct installation and ambient conditions
- Check for contamination, corrosion and damage
- Check natural voltage (e.g. buffer batteries, storage batteries)
- Check electrical/mechanical function of the connections, especially protective conductors
- Check functional elements (e.g. operating - and display devices)
- Check electrical, electronic and pneumatic input signals (e.g. sensors, remote adjustment devices, reference variables)
- Check controller functioning and actuating signal
- Check control loop as per setting parameters including all supplementary functions

### Controllers and Supplementary Modules – Maintenance when necessary
- Exchange storage batteries
- Clean to maintain functioning
- Set, adjust, tighten functional elements (e.g. operating and display devices)
- Compensate signals
- Adjust controller functioning and actuating signal
- Adjust control loop as per setting parameters including all supplementary functions

### Actuators – Periodic Maintenance
- Check for proper and functionally correct installation and ambient conditions
- Check for contamination, corrosion and damage
- Check for external leakage (e.g. valve packing bushes)
- Check electrical/mechanical function of the connections, especially protective conductors
- Check electrical, electronic and pneumatic input signals and operating range
- Check functioning of position sensors, alarm actuators and limit switches
- Readjust

### Actuators – Maintenance when necessary
- Lubricate (e.g. valve stem)
- Clean to maintain functioning

### Software – Periodic Maintenance
- Perform data back up
- Keep most recent copies of programmes and data

### Software – Maintenance when necessary
- Load most recent copies of programmes and data
Hydraulic Set

Commissioning

Caution
Observe general safety instructions on page 3!

Caution
Only use fluid with ambient temperature when charging or purging as there is a risk of scalding/frostbite.

Caution
To avoid burns, do not touch hot/cold surfaces.

Only use approved parts with ATEX units. All electrical parts must be earthed.

Ensure sufficient distance between max. surface temperature of the heat exchanger due to temperature of the medium and minimum ignition temperature of any flammable mixture which may be present in accordance with EN 1127.

Attention
Do not exceed permissible pressure range.
Observe design data sheet.

In HRS control equipment (e.g. run around coils heat recovery system) the quantity of anti-freeze is to be determined in relation to the lowest outside temperature (note manufacturer’s information).

Inspections
Check:
- Correct installation of all components.
- Inlet outlet connections for function (counter flow principle).
- Firm seating of all bolts and glands.
- Easy movement of all valves, slide dampers and baffles.

Charging
The system must be rinsed (removal of contaminations) according to VDI 2035 and should be filled with the heat exchanger fluid named in the design data sheet to the correct concentration. Water quality to VDI 2035. This control equipment charging process can also occur together with the charging of the piping system. During charging check connection points for leakage; retighten screws and glands if necessary.
**Venting**

When charging the system according to VDI 2035 the control equipment and the system should be vented carefully at the highest point of the system. Open the venting recovery device provided for this purpose. This is also valid for pumps with venting devices (e.g. high pressure centrifugal pumps in high efficiency run around heat recovery systems). Observe manufacturer’s instructions. In incompletely vented systems with pumps, air pockets may cause capacity reduction and severe damages of the pump.

**Pressure Check**

Carry out as an option following DIN 4753, part 1.

**Attention**

When doing this observe the permissible pressure stage.

**Direction of Rotation**

Check direction of rotation of pumps and servo motor. Change electrical connections if incorrect.

**Hydraulics**

Optional performance of hydraulic commissioning with setting and compensation of pressures (e.g. by using pressure regulating device).

**Steam**

In control equipment for steam the unobstructed discharge of condensate must also be checked (all condensate shut off valves must be open).
Maintenance

Venting
Pumps with venting devices (e.g. high pressure centrifugal pumps in high efficiency run around heat recovery systems) shall be vented again 2 weeks after commissioning. Observe manufacturer’s instructions. Otherwise, bearings and shaft seals might be damaged.

Maintenance Interval
Every three months. ATEX units every month.

Caution
Observe general safety instructions on page 3!

Caution
To avoid burns, do not touch hot/cold surfaces.

Caution
Before starting work allow components to cool/warm up to the ambient temperature.

Caution
Avoid any contact with brine while charging or venting. Danger of poisoning and acid burns! Observe manufacturer’s instructions.

Hydraulic Control Equipment – Periodic Maintenance
- Check control equipment for contamination, damage, corrosion and leaks
- Vent pump and hydraulic set
- Check filtering systems, clean if necessary
- Check easy movement of all valves, slide dampers and baffles; if necessary lubricate stems in accordance with manufacturer’s instructions.
- Check release pressure of pressure relief devices
- Service pumps, control valves and servo motors in accordance with manufacturer’s information

Hydraulic Control Equipment – Maintenance when necessary
- Clean control equipment and rectify any damage, leakage and corrosion
- Retighten bolts and glands

Shut Down
If out of operation for some time, especially if there is a risk of freezing, the control equipment must be emptied completely. For this purpose open all purging and discharging devices. Then blow air (compressed air, fan etc) through the control equipment for complete purging.
Shut Down

Caution
Observe general safety instructions on page 3!

If the system is to be shut down for a longer period the instructions for the individual components must be observed. Additionally it is compulsory to observe the individual component manufacturer’s information (request if necessary)!
Take the risk of freezing in winter into account in particular.

Disassembly, Disposal

Caution
Observe general safety instructions on page 3!

Only an authorised company is allowed to disassemble the unit after the service life has expired. Please observe the safety regulations for every component as well as the component manufacturer’s instructions to avoid any damage to persons or property.

All components and resources (e.g. oils, refrigerant, brine, batteries) must be disposed of in line with local regulations. All metal and plastic parts should be separated and sent for recycling.
Injection moulding parts are provided with material identification; plastic extrusions are usually made of polyvinyl chloride (PVC).
